## Introduction

This position paper discusses the problem of locally evaluating and comparing candidate schedules, in the context of a distributed scheduling task operating in unbounded environments in which each agent selfishly serves the desires and preferences of its own user.

Distributed scheduling systems have used a variety of mechanisms to maximize the quality of the global solution. Techniques include negotiation frameworks based on market economies [Kis et al. 1996], game theoretic algorithms, and global or shared evaluation functions [Modi et al. 2005]. Our position is that these techniques do not adequately address the situation where self-interested cooperative agents maintain schedules on behalf of users operating in unbounded environments. Here, satisfaction is more important than optimality [Palen 1999], and personalized preferences are paramount to users [Berry et al. 2005a; Faulring and Myers 2005]. In our approach, global utility is secondary; the agent aims to maximize the utility of its user, but folds the positive utility of cooperating with others into that utility. Thus, we treat the utility of others as a single component of a personalized and context-dependent multi-criteria evaluation function, which the agent learns through interactions with its user.

## PTIME

Our personalized time management system, *PTIME*, is part of the CALO project, a broader research program on cognitive assistance for the office environment [Mark & Perrault 2005]. A CALO agent's primary responsibility is to its user and, as such, *PTIME* aims to help a user manage her time and to optimize the time spent interacting with others. Issues of privacy, authority, cross-organizational scheduling and availability of meeting participants abound.

Tools and standards for representing, displaying, and sharing schedule information have become common, but the emphasis in the research community is automated meeting scheduling. *PTIME* is an *open* scheduling system [Ephrati et al. 1994] not operating within organizational boundaries or goals. Other examples include [Franzin et al. 2002; Payne et al. 2002; Modi et al. 2004; Faulring and Myers 2005].

The task that *PTIME* addresses is not a true distributed scheduling problem, as classically defined, but rather the loose interaction of many local scheduling problems, one

for each user. Each local *PTIME* agent accounts for its user's preferences, workload and deadlines, by formulating the local problem as a soft Constraint Satisfaction Problem [Berry et al. 2005a,b]. Soft constraints extend the classical CSP to support the concept of preferences. Each *PTIME* may access only the availability of other agents, i.e., times of free timeslots and preferences over them; information beyond this, such as the reason for a user's non-availability, can only be obtained by explicitly querying the *PTIME* of that user.

## Multi-Criteria Schedule Evaluation

The typical scheduling interaction in *PTIME* involves the user specifying constraints for one or more meetings to be scheduled, *PTIME* presenting the user with candidate schedules, and, possibly, the user requesting alternatives/variants before finally accepting one schedule. *PTIME* aims to facilitate the process of scheduling the meeting(s) by presenting good alternatives. However, the decision whether one candidate schedule is superior to another hinges on multiple criteria. Aside from satisfying constraints and preferences on meetings being scheduled (e.g., "Meeting with Bob and Carol...I'd really like Bob to be there"), a user may have general preferences for when meetings are scheduled (e.g., "I prefer morning meetings") and for the nature of her overall schedule (e.g., "I prefer my meetings back-to-back"). In addition, there are preferences common to all users such as a preference for not moving existing meetings, as well as preferences that vary between the different participants of a meeting (e.g., Bob likes meetings early in the week but Carol prefers them later).

*PTIME* adopts a multi-criteria schedule evaluation framework. Suppose Alice is scheduling a new meeting of which she is to be the host. Let  $S$  be her existing schedule,  $M$  the new meeting to be scheduled,  $S'$  the resulting new schedule, and  $M'$  the actual placement of the meeting  $M$  in  $S'$ . Note that moving existing meetings opens the possibility of  $S'-M' \neq S$ , while constraint relaxation on the new meeting request opens the possibility of  $M$  being inconsistent with  $M'$ . *PTIME*'s evaluation criteria are:

- $f_1$ : satisfaction by  $M'$  of Alice's general preferences on meetings (e.g., day of week, time of day)
- $f_2$ : satisfaction by  $S'$  of Alice's general preferences on schedules (e.g., degree of fragmentation, #meetings/day)
- $f_3$ : satisfaction by  $M'$  of meeting request constraints

- $f_4$ : satisfaction by  $S'$  of schedule constraints
- $f_5$ : stability of  $S'$
- $f_6$ : perturbation between  $S$  and  $S'$
- $f_7$ : evaluation of  $S'$  by other meeting participants

$f_1$  and  $f_2$  capture respectively how well  $S'$  satisfies Alice's general preferences over meetings and schedules, while  $f_3$  and  $f_4$  capture respectively how well  $S'$  satisfies constraints on the meeting request and on the overall schedule.  $f_5$  evaluates  $S'$  in terms of its ability to accept future changes while  $f_6$  measures perturbation from the current schedule  $S$ . Criteria  $f_1$ – $f_6$  all measure the quality of schedule  $S'$  only with respect to Alice, while  $f_7$  captures the other participants' assessment of the proposed schedule  $S'$  (i.e., its satisfaction of their own preferences and constraints).

The simplest aggregation of these criteria, a weighted sum, is inadequate because it cannot express tradeoffs users have in practice. PTIME aggregates the criteria using methods from multi-criteria decision theory, such as finding Pareto optima. Thus, Alice is presented a set of partially-ranked candidate schedules and, through the user interface, she can refine or relax her input constraints (i.e., both  $M$  and  $S$ ), to explore alternative solutions or select a preferred candidate. A similar user-centric approach is advocated by [Faulring and Myers 2005]. This exploration is supported by an explanation facility that provides visibility into why constraints may have been violated and how a new variant differs from the original.

In deciding which candidates to present to the user, PTIME has multiple objectives: (1) present desirable schedules the user is likely to accept, (2) present qualitatively different schedules to help the user explore the space of possibilities, and (3) support faster learning of preferences over criteria. We are now exploring search techniques that can produce not only a single optimal solution, but also a good set of qualitatively different solutions to meet these objectives.

### The Opinion of Others

Our informal user studies confirm that other participants' constraints and preferences often influence the meeting organizer's decisions [Palen 1999]. Within our multi-criteria evaluation, these concerns are captured by  $f_8$ , which is key to the distributed aspects of the scheduling problem.

The formation of  $f_7$  is context-dependent. At its simplest,  $f_7$  is the sum of the other user's assessments of  $S'$ , weighted according to the importance Alice attaches to their opinion:  $f_8(S') = \sum_{i \in M} \lambda_i v_i(S'_i)$ , where  $v_i$  is the assessment of user  $i$  and  $S'_i$  is user  $i$ 's new schedule.

Clearly, a requirement here is for Alice's PTIME to have knowledge of the values  $v_i(S'_i)$ . This requires communication with the other PTIME agents, and their willingness to provide this information. In turn, this leads to wider CALO issues of privacy and distributed communication (e.g., another user has his CALO switched off). If Alice's PTIME cannot ascertain one  $v_i(S'_i)$ , it by default falls back to estimation of the value. Such issues

are a further hindrance to classical distributed scheduling approaches to this scheduling situation.

Given a single candidate schedule, selected by its user, or proposed by another PTIME agent, PTIME provides a numerical value that expresses the combined evaluation of the criteria on this schedule. Hence, PTIME can respond when queried by another agent for its value  $v_i(S'_i)$ .

### Learning

Critical to the mixed-initiative goals of PTIME is the ability to use the learned knowledge of user preferences within the underlying CSP. Our initially deployed system focused on learning an individual's preferences over temporal constraints. For example, does Alice prefer morning meetings? Our current work is focused on learning a user's preferences between criteria—does Alice lend more weight to the preferences of her manager than her desire to keep her mornings free?
