## Abstract

Learning by demonstration technology has long held the promise to empower non-programmers to customize and extend software. We describe the deployment of a learning by demonstration capability to support user creation of automated procedures in a collaborative planning environment that is used widely by the U.S. Army. This technology, which has been in operational use since the summer of 2010, has helped to reduce user workloads by automating repetitive and time-consuming tasks. The technology has also provided the unexpected benefit of enabling standardization of products and processes.

## Introduction

Learning by demonstration technology has long held the promise to empower non-programmers to customize and extend software. Recent technical advances have enabled its use for automating increasingly complex tasks (Allen et al. 2007; Blythe et al. 2008; Burstein et al. 2008; Leshed et al. 2008; Cypher et al. 2010). However, fielded applications of the technology have been limited to macro recording capabilities, which can only reproduce the exact behavior demonstrated by the user.

This paper describes the successful deployment of learning by demonstration technology that goes well beyond macro recording by enabling end users to create parameterized procedures that automate general classes of repetitive or time-consuming tasks. This *task learning* technology originated as a research system within DARPA's Personalized Assistant that Learns (PAL) program, where it was focused on automating tasks within

a desktop environment (Gervasio et al. 2008; Eker et al. 2009; Gervasio & Murdock 2009).

From those research roots, PAL task learning has evolved into a fielded capability within the Command Post of the Future (CPOF)—a military command and control (C2) system used extensively by the U.S. Army. CPOF is a geospatial visualization environment that enables multiple users to collaborate in developing situational awareness and planning military operations. Much of CPOF's power comes from its generality, providing tremendous flexibility for handling a wide range of missions. The flip side of this flexibility, however, is that CPOF provides few built-in processes to support specific workflows. As a result, CPOF can require significant user interaction to complete tasks (i.e., it is "click intensive").

Task learning provides tremendous value for CPOF by enabling individual users and collective command staffs to create customized, automated information management schemes tailored to individual preferences and the staff's standard operating procedures, without needing software engineers for extensive recoding. Task learning can reduce workload and stress, can enable managing more tasks with better effectiveness, and can facilitate consideration of more options, resulting in better decisions.

In (Garvey et al. 2009), we described the core task learning technology, its integration into an initial PAL-CPOF prototype, and an extensive exercise-based evaluation of the prototype conducted by the Army in December, 2008. At this evaluation, users overwhelmingly endorsed the capabilities provided by task learning. Users stressed that task learning "saves time and that time equals lives." The results led to a recommendation by the Army to fully incorporate PAL task learning into CPOF, with the objective of deploying it for operational use.

That objective has been realized: PAL task learning has been integrated into the mainline CPOF system and its fielding was begun in the summer of 2010. The technology

is being deployed incrementally throughout the Army. For CPOF users, task learning speeds time-critical processing, eases task loads, reduces errors in repetitive tasks, and facilitates standardization of operations.

This paper describes our experiences in transitioning the initial PAL-CPOF prototype to the field, summarizing valuable lessons learned along the way. As one would expect, the deployment process involved refining and hardening the prototype capabilities along with significant systems integration work. In addition, we continuously engaged with users to ensure the technology's usability and utility. This engagement included working closely with an Army unit that was preparing for deployment, to help them incorporate task learning into their operational processes.

One unexpected outcome of the interactions with the unit was an expanded value proposition for task learning, moving beyond the original motivation of automating time-consuming processes to further include standardization of processes and products. We collaborated extensively with the unit to develop a comprehensive library of learned procedures that capture critical workflows for their daily operations. Interestingly, the unit made fundamental operational changes to take greater advantage of the automation enabled by task learning.

We begin with an overview of CPOF followed by a summary of the PAL task learning. We then describe the process of getting to deployment, covering technical challenges encountered, unit engagement activities, and an Army-led assessment of the technology. Next, we discuss the fielding of the technology, including tradeoffs made to ensure deployability, the impact of the deployed technology, and lessons learned. We close with a summary of ongoing work to deploy additional functionality and to broaden the user base for task learning in CPOF.

## Command Post of the Future (CPOF)

CPOF is a state-of-the-art command and control (C2) visualization and collaboration system. CPOF originated in a DARPA program focused on advanced user interface design for C2 environments. It grew out of a need to enable distributed command posts to process greater amounts of information and to collaborate effectively on operations. CPOF is built on the CoMotion® platform, which was derived from visualization research on SAGE (Roth et al. 1994) and Visage (Roth et al. 1996).

Three design concepts lie at the heart of CoMotion®:

*1. Information centrality.* CPOF is organized round the principle of direct interaction with information. In any C2 environment, the ability to dynamically incorporate new information is critical to the success of an operation. CPOF uses geospatial, temporal, tabular, and quantitative visualizations specifically tailored to accommodate information in the C2 domain. Though many prior visual

analytics tools operate on static data dumps, CPOF's "live" visualizations continually update in response to changes sourced from users' interactions or from underlying data feeds. CPOF is highly composable, permitting users to author new information directly in visualizations or to create composite work products by assembling multiple visualizations in a single container "product."

*2. Direct manipulation.* CPOF makes heavy use of drag-and-drop and other direct manipulation gestures to afford users content management, editing, and view control operations. By employing a small set of interactions with great consistency, simplicity and predictability emerge.

*3. Deep collaboration.* CPOF offers a deep collaboration capability, beyond pixel sharing and chat. Any visualization or composite product in CPOF supports simultaneous interaction by every user with access to it, supporting the collaborative creation of plans and analysis products. Leveraging an "over the shoulder" metaphor, sharing in CPOF happens as a natural side effect of user activities, providing shared visibility among distributed team members (just as sharing occurred naturally among co-located users in command posts prior to CPOF).

The CPOF software is part of the Army's Battle Command System, and as such is standard equipment for virtually every Army unit. Since its inception in 2004, thousands of CPOF systems have been deployed. The software is used daily at hundreds of distributed command posts and forward operational bases. CPOF spans organizational echelons from Corps to Battalion, with users in functional areas that include intelligence, operations planning, civil affairs, engineering, and ground and aviation units. CPOF is used extensively to support C2 operations for tasks covering information collection and vetting, situation understanding, daily briefings, mission planning, and retrospective analysis. A detailed description of CPOF's operational utility is provided in (Croser 2006).

The CPOF interface enables users to compose and share many "simultaneous but separate" products tailored to task and area of responsibility. One such product is a *storyboard*. A storyboard is typically created in response to a significant event, such as a downed aircraft, to provide a summary of key details, relevant operational graphics, impact analyses, and recommended actions. Other products created within CPOF include information briefings, common operating pictures, resource level estimates, and fragmentary orders.

Users can collaborate synchronously in CPOF by interacting with the same shared product. The liveness of visualizations ensures data updates flow rapidly to users, and the "over the shoulder" metaphor allows one user to monitor another's work, thus minimizing interruptions with requests for information. Collaboration group size spans the spectrum from individual (analysis, event

tracking) to small group (mission planning) to organization wide (update briefings, mission rehearsals).

Each major deployment typically has several data partitions (each a CPOF repository) that allow the Army to manage risk and redundancy for the overall system. Each major deployment has dedicated field support representatives and senior trainers residing with the unit on their bases to administer the system and support its users.

## Task Learning in PAL-CPOF

The simplicity of interaction with CPOF affords users great flexibility in creating rich visualizations over a wide variety of data. But this powerful capability often comes at the cost of time-consuming, click-intensive processes. Task learning addresses this problem by letting users automate repetitive processes, allowing them to focus on more cognitively demanding tasks. In (Garvey et al. 2009), we described the initial integration of task learning into CPOF. Here, we provide a brief overview of the learning technology, the procedure execution and editing functionality, and the triggers and workflows that together comprise the task learning capability added to CPOF.

### LAPDOG: Learning by Demonstration

The LAPDOG system (Gervasio et al. 2008; Eker et al. 2009; Gervasio & Murdock 2009) provides the learning by demonstration capabilities from the PAL program that support task learning within CPOF. Given a trace consisting of a sequence of actions performed by a user to achieve a particular task, LAPDOG generalizes the trace into a *procedure* for achieving similar tasks in the future.

LAPDOG employs a *dataflow* model in which actions are characterized by their inputs and outputs, with outputs serving as inputs to succeeding actions. LAPDOG generalizes demonstrations into procedures in two ways. First, it performs *parameter generalization*, unifying action outputs and inputs and replacing constants with variables or expressions over variables to capture the dataflow in the demonstration. Second, it performs *structure generalization*, inducing loops over collections of objects by generalizing repeated sequences of actions.

LAPDOG relies on an *action model* to provide the semantic description of the demonstrable actions in an application together with mechanisms for the instrumentation and automation of those actions. The action model for CPOF covers most of the core user activities in CPOF at a human-comprehensible level of abstraction. This abstraction comes at a higher cost of instrumentation (Garvey et al. 2009) but enables more successful generalization and facilitates understandability.

LAPDOG features the ability to infer action sequences for completing dataflow in situations where the linkage

between outputs and inputs is implicit. For example, it can query a knowledge base to infer relations between outputs and inputs. Its loop induction algorithm also supports advanced features such as the ability to learn loops that iterate over ordered or unordered collections of objects (lists and sets), involve expressions over those collections, process multiple lists simultaneously, and accumulate outputs. Loop induction is a powerful generalization technique but it has been surprisingly difficult to see it fully realized in CPOF for two primary reasons: (1) iteration is a difficult concept for end users, and (2) identifying collections in CPOF currently involves idiosyncratic gestures in the user interface.

LAPDOG was not specifically designed to learn from a single example but that has become its primary mode of use in CPOF since users have generally been unwilling to provide multiple demonstrations. LAPDOG generalizes from a single example with the aid of heuristics for filtering the set of alternative hypotheses. Specifically, it prefers more recent or more direct supports, action outputs over procedure inputs, existing procedure inputs over new ones, and loops over straight-line alternatives.

### Procedure Execution and Editing

In the initial PAL-CPOF prototype, the SPARK agent framework (Morley & Myers 2004) was used to execute learned procedures. SPARK is a feature-rich system designed to support the sophisticated control and reasoning mechanisms required by practical agent systems.

Because many CPOF users have no programming experience, it is important to provide comprehensible visualizations that communicate what a learned procedure does and to assist users in making valid edits. On the PAL project, we developed technology for procedure visualization and assisted editing (Spaulding et al. 2009). Our approach, based on feedback from user engagements, augments the action model with a flexible metadata capability to improve visualization and editing. It also employs procedure analysis techniques to detect editing problems and suggest fixes.

### Composing Higher-Level Workflows

Learned procedures provide significant value by automating functions in CPOF. Our earlier interactions with the Army revealed that the value of task learning was greatly enhanced by introducing *triggers* to enable event-driven invocation of procedures. Triggered procedures were used extensively in the original PAL-CPOF prototype to facilitate rapid response to a range of operational events.

Taking this concept a step further, it is possible to compose collections of related triggers and procedures into more complex *workflows* that automate larger chunks of functionality. Workflows open the door to automating

critical responses to significant events in accord with Standard Operating Procedures (SOPs). For example, PAL workflows have been created that automatically construct and arrange workspaces, notify selected staff of events, and prepare simple reports for the user's approval and dissemination. As discussed below, workflows proved instrumental to our deployment strategy but introduced some additional challenges.

Creating workflows requires a level of sophistication not met by most CPOF users. Successful management of workflows required us to consider classes of users with different capabilities and responsibilities. A significant part of our design effort leading up to deployment was spent creating tools and best practices to facilitate managing an ecosystem of interacting procedures, triggers, and users.

## Getting to Deployment

Our efforts to deploy the PAL task learning technology within CPOF involved two main thrusts. One focused on the hardening and refinement of the task learning capabilities, along with their integration into the mainline CPOF system. The second focused on user engagement to ensure the operational effectiveness of the technology. This section describes key challenges that arose on the technical side, along with our user engagement efforts and their impact on the development and deployment processes.

### Technical Challenges

Transitioning the task learning technology into CPOF presented numerous software engineering challenges. Even without learning, the collaboration platform and the operational domain combine to form a highly complex environment. CPOF is a fielded platform but also continues to be evolved over time. Finally, the data that CPOF manages is dynamic and voluminous.

Deployment of the technology also raised a number of challenges more directly linked to task learning. One was developing an expressive yet sustainable action model. To address this challenge, we evolved our action model framework to be extensible so that it could both grow to accommodate changes in CPOF and enable procedures from prior versions to be upgraded easily to new versions.

High-volume, concurrent procedure execution presented a second challenge. In CPOF, particularly with automatic invocation by triggers, numerous procedures can execute simultaneously. However, the PAL technology was originally developed for a personal electronic desktop assistant, for which execution typically involves small numbers of procedures generally executed one (or a few) at a time. Addressing concurrency with high volumes of procedure execution required a complete reimplementa-tion of the PAL-CPOF communications infrastructure.

Another significant challenge was the difficulty of porting PAL products (procedures or workflows) between units, which have data elements specific to their needs. Task learning generates parameters based on the data elements referenced in a demonstration. Procedures easily fit into user work processes because dependencies on the unit-specific data partition are encoded as default parameters. However, ensuring that a PAL product works for other units requires "rewiring" those defaults to the appropriate local data sources. For complex products, this *localization* process proved to be particularly demanding, requiring deep knowledge of both the author's intent and the unit's data configuration. For the initial deployment, we relied on human experts to perform this task.

### User Engagement Prior to Fielding

Our transition plan emphasized continuous user interactions to develop and refine the task learning concept in CPOF. To this end, we conducted a series of user-centered design exercises with the deploying unit. These exercises were conducted using the *Double Helix methodology* that was applied successfully to the development and deployment of the initial CPOF system. The name derives from simultaneous technology refinement based on insights from user interactions and refinement of the Concept of Operations (CONOPS) for its use within the operational domain. In the Double Helix methodology, technologists work with users in realistic settings to uncover technology issues, understand the operational "sweet spot" for the capability, and identify opportunities for its use to solve relevant operational problems.

Our Double Helix exercises yielded several insights that informed our deployment effort:

1. *Initial demonstrations of simple PAL capabilities facilitated user acceptance of the technology.* In general, introducing new technology into a large-scale, distributed operational environment requires strict feature specifications and configuration control. In addition, deployment typically requires safety and encapsulation for users with limited training while placing unfortunate restrictions on more experienced users. Such requirements run counter to the spirit of end-user task learning and could be expected to reduce user acceptance of such technology. To mitigate this risk, our engagement team introduced PAL by initially creating small procedures that automated routine, repetitive tasks rather than complex workflows. By first understanding these simple examples, users were more likely to embrace the technology and to conceive of more complex support that PAL could provide. This approach proved successful in enabling low-risk, progressive adoption of the technology.

2. *Creation of a library of automation products built by expert users greatly increased adoption of the technology.* During user engagements, we identified CONOPS common to multiple units that could be supported by generic, but sophisticated, PAL workflows. Expert users were able to automate several of these “best practice” workflows using task learning. This led to the introduction of a *PAL Library* as a way to disseminate these more advanced workflows.

The PAL Library significantly strengthened the capability deployment process. First, it conveyed to users the “art of the possible” (i.e., what can be done with the PAL technology). Prior to development of the Library, users often had limited understanding of how PAL products could help them. Afterward, there was a marked increase in capability expectations among the user base. Second, it provided complete interactive products with more compelling functionality than individual procedures. Third, it enabled users to reap the benefits of PAL without having to understand how to create procedures and triggers. Finally, the library created an effective conduit to introduce enhanced capabilities into the field.

3. *Incremental integration of PAL capabilities into operational SOPs was essential for successful technology transition.* Initial attempts to monolithically automate collaborative processes failed. Rather, PAL workflows needed to be adopted incrementally into existing SOPs. Our efforts identified one incremental adoption path: (a) an isolated workflow for a single user, (b) an individual workflow shared by multiple users, (c) a set of individual workflows within a PAL-initialized organizational process, and (d) a set of collaborative workflows supporting multiple users. Following this path facilitated incremental adoption rather than an all-or-nothing change. In this way, adoption could be “contagious.” This approach enabled use of task learning to be expanded beyond automating current SOPs to providing higher-order decision support that would not otherwise have been practical.

### **NTC Assessment**

The Army performed an assessment of the PAL software mid-way through the project to determine whether to proceed with deployment. The assessment targeted both the operational utility of the PAL capabilities and system performance metrics (e.g., bandwidth utilization, server/client performance, software quality). To enable realistic operating conditions, the Army chose to perform the assessment in conjunction with the unit’s standard three-week rotation at the National Training Center (NTC) at Ft. Irwin in May of 2010.

The purpose of the NTC rotation was to prepare the unit for operational deployment through a variety of training exercises, culminating in a “final exam” executing a

realistic mission overseen by an experienced team of Observer/Controllers. The unit was provided with an engineering release of an upcoming version of CPOF that included the learning technology and the PAL Library that they had helped to develop in the months leading up to the event. The unit had the freedom to use PAL capabilities to the extent that they found them helpful for completing their assigned mission; however, evaluation of the PAL capabilities was not an explicit objective for the soldiers.

Assessment of the PAL technology was done via a series of questionnaires that were administered to members of the unit and the Observer/Controllers. Based on the responses to these questionnaires, the Army concluded that the PAL technology significantly improved CPOF operations throughout the rotation, in certain situations reducing hours of work to minutes. A report summarizing the assessment stated that PAL capabilities “*improve a unit’s capability to efficiently execute their roles, functions and missions through better collaboration and information sharing.*” It was also determined that the PAL capabilities did not negatively impact the system performance metrics of interest. Given these results, the Army decided to proceed with the full integration of PAL task learning into CPOF and to allow the unit to deploy with the PAL capabilities.

### **Fielding**

The original plan for deployment involved a roughly two-year effort split over two phases. The first phase was to begin integration into the mainline CPOF system while concurrently developing new functionality (informed by user engagement) that would further enhance the value of task learning within CPOF. The second phase was to focus on hardening and integration, with the objective of delivering the final capability for operational deployment.

Early in the effort, the Army requested that the deployment cycle be accelerated in order to get the task learning technology into the hands of users faster. This expedited fielding led to a requirement for a hardened capability that was fully integrated into CPOF roughly nine months after the start of the effort. Not all of the planned technical functionality could be sufficiently hardened and integrated to meet this aggressive new schedule. The end result was that capabilities would be limited in the first release, with additional functionality planned for incorporation into subsequent releases of CPOF.

### **Functionality Tradeoffs**

Two main considerations determined what functionality to make available in the first deployment.

One consideration was the potential for users to teach and execute procedures with deleterious side effects, such as compromising critical data or interfering with system operation.

A second consideration was the need for training to take full advantage of the capabilities afforded by the PAL technologies. Our Double Helix interactions introduced us to the real world of deployment, redeployment, and assignment rotation, wherein the pool of users available for training changed frequently, never really reaching the critical mass of skill needed to fully understand CPOF and PAL. Indeed, many of the users with whom we interacted obtained the bulk of their CPOF knowledge through informal, on-the-job training in the form of interactions with more skilled colleagues. This sort of informal training rarely affords the trainee the opportunity to create a mental model sufficient to understand the consequences of end-user programming.

Based on these considerations, we decided not to make the learning by demonstration capability directly available to all users of CPOF in the initial deployment. Rather, a typical user could instead access pre-built procedures and workflows constructed by a small team of well-trained *Library builders*. A typical user has permission to run any available Library product (workflow or procedure) but not to extend or modify Library products, or even create stand-alone procedures that address their individual needs. Library builders have access to the core learning by demonstration capability in order to extend and modify the Library in theater. In our initial deployment, the Library builders are field support and training personnel, who are more readily trained and have greater facility with programming constructs, making it easier for them to demonstrate and manipulate procedures. It is important to note, however, that these Library builders are typically not professional software engineers and gain a great deal of flexibility and power from task learning capability.

Imposing this restriction was a difficult decision to make, as the team is fully committed to making the learning technology available to all CPOF users. Ultimately, however, we decided that it would be advisable to roll out the technology incrementally to provide some of the benefits of the learning capability while minimizing associated risks. As discussed in the Ongoing Work section below, we are continuing to extend the range of the capabilities that are available to all users of the system and are on track to deploy those in future releases of CPOF.

## **Operational Deployment**

For approximately six months beginning in late summer of 2010, a team deployed first to Iraq and then to Afghanistan to upgrade CPOF to a version containing the PAL learning technology. The upgrade team consisted of senior trainers to conduct classes and teach best practices, software developers to oversee the upgrade and collect performance and debugging information, and a unit-engagement team to help tailor and extend the PAL Library using task learning. Over several months, the upgrade team visited each of the CPOF installations and spent 2-5 weeks conducting

training classes, upgrading the repository, and providing one-on-one support.

Despite the military's reputation as a regimented organization, its processes can be surprisingly decentralized; each unit has a unique operating environment and is given a fair degree of leeway to accomplish its missions. Further, each commander sets his own operating procedures and reporting requirements. The engagement team first collected information from the unit about their local processes, then used this data to customize the generic, previously developed Library workflows to the needs of the individual unit. The engagement team iterated with the commanders and CPOF operators to teach them how to customize and use these workflows, and helped with further refinements. Concurrently, the team trained the field support representatives to provide ongoing support for the new capabilities.

There was substantial variability in adoption levels for the task learning technology. One unit that had just arrived in theater was adapting the processes left behind by the outgoing unit and welcomed the assistance to refine and automate their processes. In cases like this, the engagement team observed substantial adoption of PAL workflows and a high level of enthusiasm for the new capabilities (with one unit giving the team a standing ovation and high-fives after a demonstration of the capability). In contrast, a unit that was close to rotating out of theater had little interest in taking on the risk of new processes and tools.

One indicator of the degree of adoption of PAL was the number of modification requests received. In a few cases, the engagement team had little contact with the unit after customizing their PAL workflows and conducting training; in other cases, the team received a steady stream of requests for changes and new features. The ability to receive a requested enhancement in days to weeks rather than the typical 18-month software release cycle for CPOF generated tremendous excitement, opening the door for units to adapt CPOF on the fly to in-theater dynamics.

In several instances, the engagement team worked with users who had minimal CPOF experience. This inexperience was a disadvantage during training because it meant spending a substantial amount of time on basic system usage. However, this inexperience also provided a substantial advantage—these users drew little distinction between native CPOF capabilities and PAL enhancements. This allowed them to leapfrog their more experienced peers: rather than first learn a manual process and then understand the PAL procedures to automate that process, these users gravitated straight to using the automation.

One of the biggest lessons learned was the inverse correlation between the user-perceived complexity of a PAL workflow and the degree to which it was adopted. For example, the "storyboard creator" workflow allowed an individual soldier to create a visual summary of a

significant event in only a few clicks. This workflow fit well within existing processes and produced storyboards that looked similar to those that the soldiers created manually. As such, soldiers could incorporate this workflow into existing processes with minimal change. This incremental adoption allowed a few soldiers to try the new tools, while others took a wait-and-see approach. Adoption spread as word-of-mouth recommendation overcame initial reluctance.

On the other hand, a powerful but complex SIGACT (“Significant Action”) management workflow saw substantially less adoption. This may have been partially due to the modeled processes being overly specific to the unit that we worked with prior to deployment. Worse, its benefits were dependent on having all of the participants in the SIGACT reporting process switch to the new workflow at once. Beyond the original unit, there was little enthusiasm for moving everyone to this new process simultaneously. Based on these findings, the engagement team made modifications to the SIGACT workflow so that soldiers can use portions of it without requiring a specific prescribed reporting structure.

As units embraced the PAL technology, some began to formulate new automated workflows based on their individual operational needs. Many of these workflows centered on automating existing processes. However, a handful, such as an asset tracker, suggested entirely new unit SOPs (i.e., transitioning from manually editing text tables to automatically tracking and recording asset status), thus showing evidence of users modifying their behavior to more fully take advantage of the technology.

### **Ongoing Work**

As noted above, concerns about safety, usability, and training led to our decision to restrict access to task learning in the initial deployment. To address these concerns, we have delivered several capabilities for incorporation into the next planned release of CPOF, and are continuing to develop others for a third and final planned integration phase. We expect that incorporating these mechanisms will enable responsible extension of the task learning capability to all users of CPOF.

One strategy has been the introduction of safeguards to limit inappropriate procedure executions. These safeguards range from permissions and type checking for identifying procedures that are expected to fail during execution, to identifying loops with inordinately large numbers of iterations at execution time (which could signal a misguided application of the procedure). A second strategy has been additional support for navigating the Library, making it easier for users to locate workflows of interest and instantiate them to work in their local environments.

Finally, we have built an interactive editor within CPOF that enables users to visualize and modify learned procedures. The editor, derived conceptually from the original PAL prototype, is expected to increase understanding, and hence acceptance, of the task learning technology among basic users while providing advanced users with the means to adapt learned procedures quickly rather than demonstrating them again from scratch to incorporate changes. The ability to modify and reuse procedures created by others is particularly valuable in CPOF, where sharing is inherent to the underlying collaborative user experience.

### **Conclusions**

The PAL learning by demonstration technology has seen wide adoption within CPOF, an Army system of record employed daily by thousands of soldiers as an integral part of their mission operations. The open-ended composability of CPOF makes it an ideal target for the end-user automation enabled by the learning by demonstration technology. Although integration into CPOF presented numerous technical and operational challenges, the result is a customizable system that reduces time spent on tedious tasks while also facilitating standardization of best practices. By freeing soldiers to focus on higher-level tasks, PAL significantly improves mission-execution capabilities.

Our experiences in fielding the task learning technology to the U.S. Army offers guidance for future such efforts. User acceptance is greatly facilitated by a deep understanding of the processes that the technology will support, flexibility to allow incremental adoption, and ongoing user engagement that includes technology demonstrations to highlight “the art of the possible.”
